Problem Background

Card games often rely on simple mechanics yet remain engaging for players. From tallying values to counting occurrences, understanding the basic characteristics of a deck is a fundamental skill, especially for developing digital card game engines and applications.

Problem Description

For this problem, you'll need to build a program that will count the number of cards of a specific rank in a selected subset of cards from a standard deck. A standard deck of cards contains 52 cards; each card has a rank that either ranges from 2 through 10, or is one of "Jack," "Queen," "King," or "Ace." You'll be given an arbitrary number of cards from a deck as input, and must determine how many times a specific rank appears within those cards.

Sample Input

The first line of your program's input, **received from the standard input channel**, will contain a positive integer representing the number of test cases. Each test case will include:

- A line containing a positive integer **N**, representing the number of cards to review.
- **N** lines, each containing the rank of a card. Ranks may be an integer between 2 and 10 inclusive or one of the strings "Jack", "Queen", "King", or "Ace".
- A line containing a card rank (as described above) representing the rank to be counted.

Sample Output

For each test case, your program must print a single line containing an integer representing the number of cards of the indicated rank.
